The evolution of the infection preventionist

There is a gradual learning curve and tremendous amount of ongoing learning as new diseases, technology, and regulations force us to think differently about infection prevention.

Evolution of the global burden of viral infections from unsafe medical injections, 2000

Our model is slightly simpler than that of in that we assume that handling time associated with pathogen-immune cell interactions is negligible. In this book Ewald contests the traditional view that parasites should evolve toward benign coexistence with their hosts.

Evolution of Acute Infections and the Invasion

However, in the Caribbean where the importance of breast-feeding relative to sexual transmission is lower, natural selection on HTLV-1 does not favour any difference in progression to ATL between women and men. We then scale up the dynamics at the within-host level to the between-host level via a dose-response function, and we use the between-host model to compute epidemic curves at the population level.

Five challenges in evolution and infectious diseases

Beyond a threshold, although the maximum supportable acuteness continues to increase, the optimal acuteness does not.

Evolution of the global burden of viral infections from unsafe medical injections, 2000

There is also some indication that the virus acts differently between these two locations: significantly fewer Japanese carriers show an anti-Tax antibody response than Caribbean carriers do, which implies that the virus acts differently in the two regions and produces less Tax protein, and thus less leukaemia, in Japan. Under more realistic assumptions, a critical host population size exists, above which highly acute pathogens are buffered from extinction.
