This provides the anaerobes ample time to survive in the tissues and to activate latent collagenases. Etiologically, gentle mastication releases bacterial endotoxins from the oral cavity into the bloodstream, inducing cytokine production TNF, IL-1, and PGE 2.

More advanced forms of periodontitis are also prevalent, affecting approximately 30% moderate disease and 10% advanced disease of the adult population in the United States. New findings have suggested that tooth loss, rather than periodontal disease, may be the important link between CVD and oral health. These findings may prove valuable clinically, because impaired endothelium-dependent vasodilation induced by increased CRP serum levels may be used as a precursor in diagnosing CVD in the future.

Markers of inflammation and cardiovascular disease: application to clinical and public health practice: a statement for healthcare professionals from the Centers for Disease Control and Prevention and the American Heart Association. The therapeutic goals in periodontal disease are: first, to alter or eliminate the origin of the microbes as well as contributing risk factors, thereby preventing the progression of the disease and preserving the healthy state of the periodontium. Upregulation of proinflammatory cytokines resulting from the normal host response to an infectious agent may represent the key mechanism linking periodontal disease to PLBW.

Several amplification and suppression mechanisms are also involved in the process.

The study was the first of its kind and was quite insightful in expanding beyond P. In general, larger and more randomized populations and better controlled clinical trials will be required to substantiate the correlation of periodontal disease to these systemic conditions.

Variables leading to the latter conclusion may be due to the fact that periodontal disease is seldom present in women of birth-giving age.
