Combined with low-level moisture advection from the Gulf of Mexico, localized convection along the edge of the temperature gradient leads to precipitation generation and subsequent rainfall. Our model is sufficient to measure the sedimentary composition and volume of the entire deposit,

and to resolve the channel bodies preserved within it.

To account for this timing issue, weekly rainfall amounts were compared to weekly expected crop water demand to produce an effective rainfall estimate. The origin of Hg in these water bodies is unclear but may include atmospheric deposition, geological formations that leach Hg into the watershed, and historic land use practices.
